

Can Foundation Models Moderate Online Content?

Evaluating Instruction- vs. Example-Driven Policy Operationalization

Abstract

The growing complexity of content moderation policies presents a critical challenge for their consistent operationalization. While foundation models possess the basic capabilities needed to confront this challenge, whether they can reliably moderate online content remains an unanswered question. In this paper, we systematically compare two competing paradigms for Vision-Language Model (VLM) guidance: an *instruction-driven* approach where models reason from policy precepts, and an *example-driven* approach where they generalize from prior precedents. We ground this investigation in MODERATIONBENCH, a new benchmark of 4,000 manually annotated, in-the-wild posts from the Bluesky platform. Our experiments reveal that foundation models can substantially outperform Bluesky’s deployed moderation system, nearly tripling its F_1 score (0.60 vs. 0.22) on Random Posts in the benchmark, with both instruction- and example-driven paradigms achieving comparable peak effectiveness. Our findings thus chart a path toward reliable and adaptable policy operationalization at scale.

⚠️ Content Warning. This paper contains examples of potentially harmful or offensive content.

1 Introduction

Content moderation encompasses the activities platforms undertake to detect content that violates their established norms of acceptable behaviors (EU, 2022). These established norms have gradually evolved into intricate policies spanning over several thousands of words (see Table 1). Such policies are typically comprised of three distinct components: specific *policy labels* for detecting violations (*the what*), overarching *policy rationale* (*the why*),

Platform	Label descr.	+ Rationale	+ Details	= Policy
 Bluesky	242	1,574	1,198	3,014
 X	423	2,668	6,321	9,412
 TikTok	2,810	1,993	5,840	10,643
 Meta	1,854	3,156	21,288	26,298

Table 1: Complexity of content moderation policies, measured by the *word count of policy components*.

and granular *policy details* for enforcement (*the how*) (Bluesky, 2025; Meta, 2026). Simultaneously synthesizing and applying these detailed policies to every unique and nuanced context imposes an unsustainable cognitive load on human moderators, increasing the reliance on automated moderation.

However, these automated systems often rely on brittle pattern-matching and rule-based models that fail to grasp the desired contextual nuances (Halevy et al., 2022; Bluesky, 2026; Singh et al., 2026). Unlike these brittle systems, emerging *foundation models* are trained on internet-scale multimodal data, endowing them with a rich world model and a deeper capacity for contextual reasoning (Brown et al., 2020; Vafa et al., 2024). In principle, their ability to comprehend and execute complex instructions makes them a promising candidate to address the policy complexity that challenges human moderators. However, it remains an open question whether this general-purpose reasoning can be reliably translated to the multi-layered, and high-stakes task of enforcing a platform’s norms. This gap between theoretical promise and practical application brings us to the guiding question for this research: *Can foundation models moderate online content?*

To answer this question, we introduce MODERATIONBENCH, a moderation benchmark grounded in the real-world ecosystem of the Bluesky social media platform. Each post in MODERATIONBENCH contains a combination of text and potentially several images, reflecting the multimodal nature of real-world social media content. Moreover, these posts were manually reviewed and labeled by our

team, providing an example of human operationalization of Bluesky’s complex moderation policies.

Using this benchmark, we systematically evaluate a range of open-weight and frontier Vision-Language Models (VLMs), including a specialized AI safety model, under two competing paradigms: *instruction-driven* and *example-driven* moderation. The *instruction-driven* paradigm takes a top-down approach, where models moderate online content directly using the policy framework across the axes identified previously: policy labels, rationale, and enforcement details. In contrast, the *example-driven* paradigm takes a bottom-up approach, asking models to generalize from prior moderation decisions. Within this paradigm, we evaluate three example-selection strategies: (a) *random*, (b) *prototypical*, and (c) *contextual* examples.

Our investigations yield five key findings:

- (a) Our proposed MODERATIONBENCH exposes a significant coverage gap in Bluesky’s deployed moderation system: human annotators found nearly 35% of posts semantically similar to moderated content were unsafe and missed by the platform.
- (b) Instruction-driven foundation models outperform the current Bluesky moderation system, achieving nearly triple its F_1 score on Random Posts (0.60 vs. 0.22). Open-weight models deliver competitive performance to their frontier counterparts (0.52 F_1 for gemma4 vs. 0.60 for gemini3.5).
- (c) Within the instruction-driven paradigm, granular policy details are critical in boosting moderation consistency and effectiveness: roughly halving flagging rates and improving F_1 scores by up to 25%.
- (d) The best example-driven approach using prior moderation examples achieves nearly identical F_1 performance (0.59 vs. 0.60 for gemini3.5) on Random Posts. This parity, however, comes at a severe practical cost, increasing inference latency by over $6\times$ for open-weight models and $\approx 3\times$ higher cost and time for frontier models.
- (e) Specialized AI safety models (llama-guard) are ineffective for out-of-the-box moderation. On Random Posts, it achieves significantly lower F_1 than its base model (0.14 vs. 0.44). Furthermore, providing the full platform policy fails to close this performance gap, indicating a lack of steerability.

2 Related Work

Content Moderation in Practice. Content moderation policies (Bluesky, 2025; Meta, 2026) vary substantially across platforms (Gillespie, 2018) and

have grown increasingly complex (Inserra, 2024). Hence, at scale, major platforms increasingly rely on automation, as reflected in EU Digital Services Act disclosures (Trujillo et al., 2025; Shahi et al., 2025; Kaushal et al., 2024). However, existing rule-based pipelines remain brittle (Bluesky, 2026; Halevy et al., 2022), leading to the central, previously unexplored, question of the current work: *can foundation models moderate online content?*

We study this through *policy operationalization*: translating abstract policy goals into concrete moderation decisions. Inspired by two legal traditions—*Civil Law*, which emphasizes codified rules, and *Common Law*, which draws on prior rulings (David and Brierley, 1978)—we systematically evaluate two corresponding approaches in foundation models: policy instructions and example decisions.

Safety of AI Models. While our work focuses on AI models for content moderation, a related line of work addresses the safety of AI models. While system prompts are commonly used to steer model behavior, their reliability as a governance mechanism remains an open question (Neumann et al., 2026). As a complementary approach, AI safety models have been fine-tuned to classify unsafe prompts and AI-generated outputs against predefined harm taxonomies (Helff et al., 2024; Meta AI, 2025). However, it remains unclear whether these specialized models can be steered via prompting to moderate multimodal online content.

Benchmarks for Content Moderation. To answer these questions, we need policy-grounded moderation benchmarks. To this end, early benchmarks targeted specific harms in single modalities—hateful texts (Mathew et al., 2021; Sap et al., 2020) and graphic images (Moreira et al., 2016; Demarty et al., 2015). Recent works broaden harm coverage, but remain uni-modal, relying on images from search engines (Qu et al., 2025; Li et al., 2024), AI-generated content (Wang et al., 2025b), or synthetic labels (Yeh et al., 2024). Existing multimodal benchmarks (Das et al., 2023; Kiela et al., 2020) address only hate speech through memes.

More fundamentally, no existing benchmark is grounded in a deployed platform: providing neither human annotations under platform-specific policies nor the platform’s own moderation decisions as a reference. MODERATIONBENCH addresses these gaps by enabling *first direct comparison between VLM capabilities and deployed moderation systems in detecting diverse harms on in-the-wild content*.

3 Curating MODERATIONBENCH

Data Collection from Bluesky. Bluesky’s open architecture provides two public data streams (Kleppmann et al., 2024; Singh et al., 2026): (i) the *firehose* (com.atproto.sync.subscribeRepos), containing all platform posts, and (ii) the *label stream* (com.atproto.label.subscribeLabels), containing moderation labels assigned by the Bluesky Moderation Service (BMS). From March–December 2025, we collected 1.14B posts and 11.9M BMS labels. We additionally curated 844K posts from 194 verified organizational accounts spanning news media, science and technology, academia, government, and NGOs.

3.1 MODERATIONBENCH

We curate four datasets of multimodal posts (*text with potentially multiple images*) from our large collection, each targeting a specific evaluation axis.

Random Posts. Harmful posts are naturally sparse within largely benign platform traffic, making detection challenging. This subset asks: *How effectively can harmful posts be identified in the wild?* We uniformly sample 1,000 posts from the firehose, preserving the natural content distribution.

Moderated Posts. BMS primarily applies nine labels through a Human-AI pipeline (Bluesky, 2026). porn, sexual, figurative, nudity, graphic-media, and self-harm are automated via Hive (Appendix B), while rude, intolerance, and threat are assigned by human moderators. This subset asks: *How accurately can harmful posts already flagged by a deployed system be identified?* We randomly sample 1,000 BMS-labeled posts balanced across the nine categories.

Near-moderated Posts. Advances in moderation systems should also detect harmful content missed by the existing deployed system. This subset asks: *Can moderation coverage be extended to harmful posts that went unflagged?* We select the 1,000 unmoderated firehose posts *semantically most similar* to those in Moderated Posts, making them strong candidates for missed harmful content. We provide additional data collection details in Appendix A.

Safe Posts. A well-calibrated moderation system should avoid over-flagging benign content. This subset asks: *How prone is a moderation system to false positives?* We sample 1,000 posts from verified organizational accounts, where harmful content is expected to be rare.

Subset	Human(%)	BMS(%)
Random	2.7%	0.6%
Moderated	83.7%	100%
Near-moderated	34.6%	0.0%
Safe	0.0%	0.0%

Table 2: Human consensus and BMS unsafe flagging rates across the four MODERATIONBENCH subsets.

3.2 Human Policy Operationalization

Alongside dataset curation, we manually annotate every post in MODERATIONBENCH, producing a human operationalization of BMS policy labels that serves as our *reference standard*. Two co-authors independently assess the complete multimodal content of each post—text, images, and thumbnails where present—assigning (i) a binary safety judgment (safe/unsafe) and (ii) harm labels following Bluesky’s taxonomy. Disagreements are resolved by a third co-author, and our annotations yield substantial inter-annotator agreement (Cohen’s $\kappa = 0.813$). Further details about the annotation process are provided in Appendix A.

Human Flagging Rates. Table 2 reports human flagging rates across MODERATIONBENCH. As expected, Safe Posts contains no unsafe posts, while only 2.7% of Random Posts is unsafe, reflecting the low prevalence of harmful content in the wild. In Moderated Posts, 83.7% of posts are judged unsafe, confirming that the BMS largely identifies genuinely harmful content. Notably, 34.6% of Near-moderated Posts is judged unsafe despite receiving no BMS label. These rates validate MODERATIONBENCH’s design and expose a coverage gap in Bluesky’s deployed moderation pipeline: harmful content can remain undetected even with a hybrid Human-AI system.

Models Benchmarked. Motivated by the limitations of Bluesky’s deployed system and the multimodal nature of the posts, we evaluate *foundation* Vision-Language Models (VLMs) as candidates for content moderation. We benchmark both *instruct-tuned* and *reasoning* models from *open-weight* and *closed, API-based* families. A detailed list of models and practical details is in Appendix E. For inference, we set the temperature to 0 for deterministic results, and report summary statistics over each dataset, model, and setup.

4 Instruction(Code)-driven Moderation

Deploying VLMs for moderation requires equipping them with details (Palla et al., 2025) about a platform’s policies. We explore *instruction-driven*

Part	Rules	Words	Description
Labels	11	242	Definition per content label, including other-unsafe & safe.
Rationale	88	1,574	Four principles & guidelines on protected expressions.
Details	78	1,198	Per-label scope of violations & carved-out exceptions.

Table 3: Bluesky content moderation policy structure.

moderation by supplying VLMs with varying levels of Bluesky’s policy.

4.1 What, Why, and How to Moderate?

We identify three axes of instructions for communicating moderation needs to VLMs. Table 3 summarizes these axes for Bluesky’s moderation policy.

Policy Labels (*What?*): VLMs must know *which harms* to detect. We provide this via *Label Descriptions*—label names and descriptions provided by Bluesky (Bluesky Moderation Service).

Policy Rationale (*Why?*): VLMs must be conveyed the *principles* (e.g., platform safety, respectful discourse, etc.) behind moderation mentioned in Community Guidelines (Bluesky, 2025).

Policy Details (*How?*): This axis concerns the *operationalization* of policies: the specific *Rules* governing labeling. Since human moderator rules are not publicly disclosed, we instead supply the Hive API’s rules for the labels it automates in the prompt.

To assess the impact of instruction granularity, we evaluate four prompt configurations: policy labels (*What*), policy labels with rationale (*What & Why*), policy labels with details (*What & How*), and policy labels with rationale and details (*What, Why & How*). Further details on the prompt construction are provided in Appendix C with additional analyses in Appendix F.

4.2 Effectiveness of Moderation Decisions

We first use MODERATIONBENCH to evaluate whether VLMs can effectively operationalize platform policies through granular instructions.

Granular instructions consistently improve VLM effectiveness. In Fig. 1, we show F_1 scores of different VLMs with different policy granularities on Random Posts. Model performance improves with richer instructions: policy rationale (*Why*) yields gains over labels (*What*), particularly for qwen models, while policy rules (*How*) drive higher F_1 across all models. This trend is consistently observed across all models: for instance, llama4’s F_1 improves significantly when given the full de-

Figure 1: Incorporating granular policy details improves moderation effectiveness (F_1) on Random Posts.

Figure 2: Flagging rate of models on Random Posts for different policy setups. Models become less sensitive to flagging as more granular instructions are provided.

tails (*What, Why, & How*). The frontier models, i.e., gemini3.5 and gpt5.6, also reflect this trend. Interestingly, most VLM setups improve upon the deployed Bluesky Moderation Service (BMS) on Random Posts, and the best-performing open models are gemma4 and qwen3.5. Hence, in the following analyses, we consider these two open models alongside the frontier models.

To understand why increasing policy granularity improves F_1 on Random Posts, we analyze VLM *binary flagging rates* (safe vs. unsafe) in Fig. 2. We find that *detailed instructions make VLMs more conservative*. Flagging peaks when only labels (*What*) are provided, substantially exceeding human-annotator rates. Adding policy rationale and details reduces flagging, bringing gemma4 and qwen3.5 closer to human levels. Although flagging increases slightly with *What, Why & How* compared with *What & How*, it remains below that with limited policy information. Thus, richer policy context reduces unnecessary flagging and brings VLMs closer to human judgments.

VLMs outperform BMS. Having shown that granular policy instructions improve performance on Random Posts, we now compare instruction-driven VLMs against the currently deployed BMS across MODERATIONBENCH. Table 4 reports results using the complete policy specification.

VLMs achieve substantially higher F_1 than the BMS on Random Posts, driven by higher recall. On Moderated Posts, VLMs perform strongly and even exceed BMS regarding precision, sug-

Data	Model	Precision	Recall	F ₁
Random	gemma4	0.42	0.67	0.52
	qwen3.5	0.44	0.62	0.52
	gemini3.5	0.55	0.67	0.60
	gpt5.6	0.31	0.58	0.41
	BMS	1.00	0.12	0.22
Moderated	gemma4	0.87	0.97	0.92
	qwen3.5	0.88	0.96	0.92
	gemini3.5	0.88	0.97	0.92
	gpt5.6	0.87	0.98	0.92
	BMS	0.83	1.00	0.91
Near-moderated	gemma4	0.75	0.88	0.81
	qwen3.5	0.72	0.84	0.77
	gemini3.5	0.80	0.87	0.83
	gpt5.6	0.72	0.86	0.79
	BMS	0.0	0.0	0.0

Table 4: Effectiveness of VLM moderation (with Labels, Rationale, & Details) compared to deployed BMS on different data subsets. No model flagged Safe Posts.

gesting that Bluesky itself is not immune to over-flagging. Neither system flags any Safe Posts.

The largest difference appears on Near-moderated Posts, where VLMs achieve high precision, recall, and F_1 , while the BMS scores zero across all metrics despite human annotators judging $\approx 35\%$ of posts as policy-violating. Although expected since these posts are, by construction, left unmoderated by the BMS, this result shows that instruction-driven VLMs can identify many policy-violating, near-boundary posts missed by the deployed pipeline.

Open-weight models are competitive with frontier models. The strongest open-weight VLM, gemma4 (31B), performs comparably to the frontier model gemini3.5, with slightly lower performance on Random Posts and comparable results on Moderated and Near-moderated Posts. Thus, instruction-driven moderation with open-weight VLMs can match frontier models while outperforming a live platform’s deployed moderation system.

Practical Efficiency of VLMs. Given their moderation effectiveness, we assess whether open-weight VLMs are practical at scale. Richer policy instructions add only modest runtime overhead: gemma4, for example, processes text+image posts at ≈ 49 posts/minute with the complete *What, Why & How* policy, compared with ≈ 61 using only labels. Latency is driven primarily by the model and input modality (Appendix F.3). Combined with their effectiveness close to frontier models, this throughput makes open-weight VLMs promising for *aiding scalable moderation* without potentially substantial frontier-model API costs (gemini: \$26–\$49; gpt: \$17–\$63 per setup over MODERATIONBENCH, in-

Figure 3: Moderation decision flows between gemma4 & qwen3.5 on Moderated. *Decisions are largely consistent, with systematic patterns among disagreements.*

creasing with policy granularity). Evaluating this potential in live, streaming settings remains an important direction for future work.

4.3 Consistency in Moderation Decisions

Content moderation is inherently subjective (Alipour et al., 2026): VLMs may differ in decisions or justify decisions using different policy parts. We therefore study both *decision consistency* (if models predict the same label) and *judgment consistency* (if they rely on similar policy rules).

Decision Consistency. Fig. 3 compares predictions from gemma4 and qwen3.5 under complete policy instructions (*What, Why & How*). The dominant diagonal flows show that the models usually assign the same label. This holds quantitatively across model pairs and instruction levels (Appendix F.5); for example, gemma4–qwen3.5 achieves Gwet’s AC1 of 0.78 on Moderated Posts, with higher agreement on the other subsets. Predictions are also stable within models as instruction granularity changes, with 95–96% remaining unchanged across settings (Appendix F.4.1). Frontier-model comparisons show similar patterns (Figures 14–15).

Judgment Consistency. Since decision agreement is lowest on Moderated Posts (Appendix F.5), we analyze this subset in greater depth by asking models to provide a short justification and supporting policy excerpts (Appendix C.3).

Models cite only a small subset of the policy. Fig. 16 shows that models rely on a limited subset of the 177 policy rules: 50.3% are never cited by gemma4, 47.5% by qwen3.5, and 40.1% by either

Figure 4: Each X-axis point represents a rule in the Bluesky moderation policy, grouped by policy part; the Y-axis shows its citation frequency for gemma4 (top) and qwen3.5 (bottom) when their moderation decisions disagree. Differences in the distributions reflect *differences in policy judgment* underlying these disagreements.

model. Within the *Rationale* component (Table 3), for example, citations concentrate on a handful of rules under *Safety First* and *Respect Others*.

Models cite similar rules when decisions agree. When the models predict the same label, their policy citation distributions also align (Fig. 17), with high Spearman rank correlation ($\rho = 0.82$) and low Jensen–Shannon divergence (JSD= 0.08).

Disagreements and Pluralism. When decisions disagree, policy citations diverge substantially (Fig. 4): Spearman correlation drops to $\rho = 0.58$, and JSD rises to 0.36. The same pattern holds across open- and closed-weight models (Figures 18–20); for example, gemma4–gemin3.5 shifts from $\rho = 0.87$, JSD=0.05 when decisions agree to $\rho = 0.48$, JSD= 0.40 when they disagree.

Moderation disagreements show distinct patterns. Fig. 3 reveals two prominent shifts: (i) *pluralism in unsafe categorization*, where, e.g., adult content labeled sexual or figurative by gemma4 is often labeled porn by qwen3.5; and (ii) *pluralism in safety adjudication*, where, e.g., content labeled rude by gemma4 is often considered safe by qwen3.5. Policy citations reflect these shifts (Fig. 4): for adult content, gemma4 more often cites rules for sexual and figurative, whereas qwen3.5 cites porn; for rude–safe disagreements, gemma4 more often cites the rude definition, whereas qwen3.5 cites the exception rules (*Details (Notes)* in the figure).

Table 8 illustrates these interpretive differences. For example, for “Christ can lick my dirty a**hole. You can too.”, gemma4 focuses on targeting Christian sentiments and labels it intolerance, whereas qwen3.5 focuses on the crude language and labels it rude.

Qualitative Assessment. To assess whether one interpretation is clearly preferable, two authors independently evaluated each disagreement along

two dimensions: (i) the better moderation decision and (ii) the better policy support for each model’s own decision, independent of (i). For each, annotators selected gemma4, qwen3.5, both, or neither. Agreement was only *fair* (Cohen’s $\kappa = 0.27$ for decisions; 0.25 for policy support), showing substantial subjectivity. For the example above, one annotator selected both models on both dimensions, while the other preferred gemma4 on both.

Human preferences vary across disagreement types. For sexual $\rightarrow$ porn, annotators preferred gemma4’s decisions in 89% of cases and its policy support in 79%; for figurative $\rightarrow$ porn, these rates drop to 62% and 65%. Overall, gemma4’s policy support is preferred in 51% of disagreements. The rude–safe cases are more subjective: annotators agree on the preferred policy support in 60% of cases, but on the preferred decision in only 40%.

Overall, VLM disagreements reveal distinct ways of operationalizing the same policy. Understanding and reconciling these differences, for example, using techniques inspired by cognitive interviews, is an important direction for future work, as is examining whether they produce systematic biases.

5 Example(Case)-driven Moderation

Beyond instruction-driven guidance, VLMs can also be guided to solve novel tasks through in-context examples. We investigate whether this capability extends to moderation by providing prior multimodal moderation decisions from the Bluesky Moderation Service (BMS).

5.1 Moderated Content as Examples

We evaluate three strategies for selecting in-context example posts, each capturing a different notion of a useful moderation precedent.

Figure 5: Prototypical examples perform better on Random Posts in the example-driven paradigm.

Data	Model	Flag %	Precision	Recall	F ₁
Random	gemma4	7.1	0.31 _{↓0.11}	0.92 _{↑0.25}	0.47 _{↓0.05}
	gemini	3.0	0.53 _{↓0.02}	0.67 _{±0.00}	0.59 _{↓0.01}
	gpt	7.8	0.27 _{↓0.04}	0.88 _{↑0.30}	0.42 _{↑0.01}
	BMS	0.3	1.00	0.12	0.22
Moderated	gemma4	95.6	0.85 _{↓0.02}	0.98 _{↑0.01}	0.91 _{↓0.01}
	gemini	90.8	0.89 _{↑0.01}	0.97 _{±0.00}	0.93 _{↓0.01}
	gpt	96.4	0.85 _{↓0.02}	0.99 _{↑0.01}	0.91 _{↓0.01}
	BMS	100.0	0.83	1.00	0.91
Near-moderated	gemma4	48.1	0.70 _{↓0.05}	0.98 _{↑0.10}	0.82 _{↑0.01}
	gemini	38.0	0.81 _{↑0.01}	0.88 _{↑0.01}	0.84 _{↑0.01}
	gpt	52.0	0.63 _{↓0.09}	0.95 _{↑0.09}	0.76 _{↓0.03}
	BMS	0.0	0.0	0.0	0.0

Table 5: *Example-driven* (Prototypical) moderation effectiveness compared to BMS. Subscripts denote delta vs. *instruction-driven* (full policy) prompting (Table 4); gpt flags 0.93% of Safe Posts while others flag none.

Random. Ten examples per label are randomly sampled from BMS-moderated posts, capturing violation diversity without selection bias.

Prototypical. Ten examples per label are selected as the posts closest to the mean embedding of all posts assigned that label, capturing the characteristic exemplar of each violation.

Contextual. Ten examples per label are selected dynamically as the semantically most similar BMS-moderated posts to the post under review.

Additionally, *ten safe posts* from our curated collection are provided. Appendix D provides further details; Appendix G shows additional evaluations.

5.2 Effectiveness of Moderation Decisions

Prototypical examples perform the best across all models. Fig. 5 shows F_1 scores across VLMs and setups on Random Posts. Most VLMs show their strongest performance with prototypical examples, where even some of the weaker models such as qwen3-vl, mistral3, and magistral outperform the BMS. However, the performance diminishes greatly with contextual examples. As observed in the instruction-driven setting, this performance drop can be attributed to increases in flagging rates. Specifically, with contextual examples, VLMs over-flag content as particular categories like rude.

Frontier models handle examples as effectively as detailed instructions. Table 5 reports the effec-

tiveness of VLMs in the example-driven setting (with *prototypical*) across MODERATIONBENCH. Even with examples, gemini3.5 remains the best-performing model, and gpt5.6 becomes the third-best-performing model. Gemma4 is *the only open-weight VLM* to effectively handle examples, sitting between the two frontier models. In contrast, compared to the instruction-driven paradigm, other open-weight VLMs, e.g., the qwen models, show a performance drop in the example-driven paradigm.

Policy guidance from both paradigms improves moderation beyond label definitions. Label definitions alone provide limited information about how a platform conducts moderation. Both paradigms provide additional platform-specific guidance: instruction-driven through textual policy details and example-driven through prior moderated and safe posts. Figures 1 and 5 show that *both forms of guidance improve performance* over the labels-only setting. For top-performing models such as gemini3.5 and gemma4, the best performance under the two paradigms is comparable ($F_1 \approx 0.6$ and 0.5 , respectively). Overall, however, textual policy details yield more consistent gains, particularly for open-weight VLMs. Moreover, as we discuss below, example-driven prompting is substantially less efficient because it requires processing additional images.

Practical Efficiency. Despite comparable performance for the best-performing models, example-driven moderation incurs *substantially higher computational and usage costs*. With prototypical examples, gemma4 processes around 10 posts/minute, $\approx 6.5\times$ slower than with full policy details, due to the multiple multimodal in-context examples included with each query. For frontier models, labeling costs across MODERATIONBENCH are $2.7\times$ (gemini3.5) and $32\times$ (gpt5.6) higher than in the instruction-driven setting. These higher costs bring *no performance gain* over the best instruction-driven setting, weakening the practical case for example-driven moderation. Further details are provided in Appendix G.3.

5.3 Consistency of Moderation Decisions

Figures 25 and 26 (Appendix G.4) compare moderation labels predicted by the best-performing models (gemma4 and gemini3.5) as well as between the two closed models (gemini3.5 and gpt5.6), respectively, under the best example-driven setting (prototypical). The dominant diagonal flows indicate that models are largely con-

Posts	Model (policy)	Flag %	Precision	Recall	F_1

	mistral (Bsky)	53.85	0.61	0.95	0.75
Safe	llama-guard (Own)	15.34	0.00	–	–
	llama-guard (Bsky)	4.46	0.00	–	–
	llama4 (Bsky)	1.97	0.00	–	–
	shieldstral (Bsky)	7.25	0.00	–	–
	mistral (Bsky)	1.55	0.00	–	–

Table 6: AI safety models (llama-guard: Own/Bluesky; shieldstral: Bluesky policy) underperform corresponding general-purpose VLMs (llama4, mistral) for multimodal content moderation.

sistent in their moderation decisions. We further quantify inter-model agreement using Gwet’s AC1 (Appendix G.4). On Moderated Posts, for example, gemma4–gemini3.5 achieve high agreement ($AC1 = 0.82$) with prototypical examples, with higher agreement on the other subsets. Moderation decisions also remain largely consistent across the two prompting paradigms. In Appendix H.1, we show how, for gemma4, predictions remain largely consistent between instruction-driven with full policy and example-driven (prototypical) paradigms. Taken together, while the example-driven approach is comparable in terms of its effectiveness and consistency with the instruction-driven approach, this parity often comes at a significantly higher cost.

6 AI Safety Models for Moderation

Having evaluated general-purpose VLMs for multimodal content moderation, we now examine specialized *AI safety models* trained to detect unsafe user prompts and AI-generated responses, asking whether they transfer to real-world social media moderation under the Bluesky policy effectively.

We evaluate two recent multimodal safety models: llama-guard4-12B (Meta AI, 2025) and shieldstral (Calvi et al., 2026). llama-guard is fine-tuned for its own safety taxonomy, so we evaluate it both under its native taxonomy (Own) and with the complete Bluesky policy supplied at inference time (Bluesky) to assess how well it adapts to a different moderation policy. We further compare it against its base instruct model,

llama4-scout, to quantify the effect of safety fine-tuning. In contrast, shieldstral is fine-tuned to support different moderation policies at inference time. We evaluate it under the Bluesky policy and compare it against its corresponding base model, mistral. Table 6 summarizes the results.

Safety models are ineffective for content moderation. Using its native taxonomy, llama-guard performs substantially worse than llama4 across all subsets of MODERATIONBENCH. It severely over-flags benign content in Random and Safe Posts, while under-flagging unsafe content in Moderated and Near-moderated Posts, resulting in consistently lower F_1 scores. shieldstral performs comparably to mistral on the more harmful subsets (Moderated and Near-moderated Posts), but also over-flags Random and Safe Posts, reducing precision and overall F_1 .

Safety models specialized to a fixed taxonomy are difficult to steer. Replacing llama-guard’s native taxonomy with the Bluesky policy reduces false positives on Random Posts and Safe Posts and improves overall performance. However, it remains consistently worse than its base instruct model across all four subsets, suggesting that fine-tuning to a fixed safety taxonomy limits adaptation to platform-specific moderation policies through prompting alone. Appendix H.2 further analyzes the models’ decision disagreements, highlighting where llama-guard over-flags benign content or misses harmful posts.

Overall, these results suggest that specialized AI safety models do not outperform general-purpose VLMs for platform moderation. Models specialized to a fixed taxonomy lack the flexibility needed to adapt to different moderation policies, while policy-adaptive safety models retain high recall but remain prone to over-flagging.

7 Conclusion

In this paper, we asked whether foundation models can reliably operationalize complex content moderation policies. To answer this, we introduced MODERATIONBENCH, a new benchmark grounded in the Bluesky platform, and conducted the first systematic comparison between *instruction-driven* and *example-driven* paradigms for VLM guidance. Our findings are unambiguous: while foundation models (using both paradigms) are able to outperform currently deployed moderation systems, the instruction-driven paradigm seems to be more adept at scaling for deployment at platform scale.

Our study represents a first step and is not without limitations (discussed below). Nonetheless, even with its limitations, by answering a fundamental question of policy operationalization, we believe this work lays a meaningful foundation for transparent and adaptable platform governance.

Limitations

This study has several limitations that point to important directions for future work.

First, social media content extends beyond text and images to include videos and audio. Our evaluation does not address these modalities, and understanding how their inclusion affects VLM moderation performance remains an open question we leave for future work.

Second, our focus is on how effectively VLMs can be steered to operationalize platform-specific moderation policies and on comparing instruction-driven and example-driven moderation. While our consistency analysis shows that disagreements between VLMs largely reflect different interpretations of the same policy rather than random variation, we do not examine whether these differing interpretations lead to systematic *biases* in moderation outcomes. Such biases are inherently multifaceted: disparities may concern the demographics of content creators, the demographics of the targets of harmful content, or both, and may originate from the underlying VLM, the platform policy itself, or the example moderation decisions used to guide the model. These represent distinct sources of bias that require different evaluation methodologies and mitigation strategies. Given the high stakes of such disparate impacts, a comprehensive bias evaluation is an important direction for future work and was beyond the scope of the current work.

Third, we treat each post as an atomic unit, overlooking the role of *surrounding context*. This is particularly important for labels such as rude, where a reply may depend on the broader conversation thread. Future work should incorporate richer platform context, including conversation threads for bullying, external sources for fact-checking, and platform-wide activity for spam detection. Collecting and representing such context for VLM-based moderation remains an open challenge.

Fourth, posts frequently contain *links to external sources* where the actual harmful content resides. Our study does not account for this, and understanding how retrieving and incorporating linked

content shapes VLM moderation decisions remains an important avenue for research.

We also acknowledge that MODERATIONBENCH currently does not include *annotations from expert moderators*. Obtaining expert judgments, particularly for political and other subjective categories, would strengthen the evaluation and is an important direction for extending this work.

Finally, real-time moderation at platform scale poses substantial computational and practical challenges. While we evaluate VLM throughput on a static dataset, we do not assess scalability or effectiveness in live, streaming settings. Moreover, platform policies and taxonomies evolve over time. Instruction-driven moderation can accommodate such changes by directly providing updated policies to VLMs, offering a potential advantage over supervised approaches that may require new annotations and fine-tuning. However, how policy changes affect VLM moderation decisions and policy interpretations in practice remains an open question. Evaluating VLM-based moderation under evolving policies and at live-platform scale is therefore an important direction for future work.

Ethical Considerations

Our research is grounded in a commitment to ethical and responsible analysis. The study relies exclusively on publicly available data—social media posts comprising text and images—with no collection of non-public account data or direct user interactions. All annotations were performed by the co-authors, and this work does not constitute human-subjects research.

All data storage and processing were conducted on secure institutional infrastructure, with no data shared with external parties. Our benchmark was designed to minimize risk: we used open-weight models and open-source tools deployed entirely in-house, without interacting with platform users, deploying automated agents, or manipulating platform behavior in any way. All results are reported using aggregated or non-identifying statistics.

Because the dataset contains sensitive, explicit, and graphic content, we will release it to the research community in a *gated manner for non-commercial use only*. This work carries no significant risks of misuse, as our use of foundation models is directed at *detecting* harmful content on online platforms—not circumventing or jailbreak-

ing existing AI systems. We are confident that the positive impact of this work substantially outweighs any associated risks.

Generative AI Statement

Generative AI assistants such as Claude Sonnet and ChatGPT were utilized to correct grammar and the structuring of text in the manuscript. These assistants were also used to assist in implementing specific helper functions in the code and for certain visualizations reported in the manuscript. However, the core implementation and the draft of the manuscript were generated by the authors. Moreover, all text and code revisions provided by AI models were reviewed and appropriately revised by the authors before final usage.

A Data Gathering and Curation

Here, we detail our data collection procedure from Bluesky and the corresponding benchmark curation. Our data gathering procedure closely follows prior work on characterizing Bluesky’s content moderation system (Singh et al., 2026).

Firehose Collection. Using the `com.atproto.sync.subscribeRepos` endpoint, we collected firehose events between March and December 2025, yielding 1.14B post records (events of type `app.bsky.feed.post`), of which 11.9M ($\sim 1\%$) were labeled by BMS. Each post record contains the post text, creation timestamp, and optional embedded media content identifiers (CIDs); we retrieve the corresponding blobs (images, thumbnails, videos) via `com.atproto.sync.getBlob`.

Random Posts. We select an equal number of posts from each month between March and December 2025, resulting in a total of 1,000 posts. This data is gathered from the firehose that has been mentioned previously.

Moderated Posts. We collect the label stream for Bluesky Moderation Service for 2025 via the `com.atproto.label.subscribeLabels` endpoint and retrieve the corresponding post records using `com.atproto.repo.getRecord`. Figure 6 shows the distribution of label applications across harm labels: a small set of labels dominates, with the top labels accounting for the vast majority of all applications. We focus our analysis on nine harm categories that target post-level content: intolerance, rude, threat, graphic-media, self-harm, porn, sexual, figurative, and

Figure 6: CDF of labels applied across harm labels on Bluesky. A small number of labels account for the vast majority of applications; we focus on the nine post-level harm categories (excluding spam, which reflects account-level behavior).

nudity. We exclude spam, as it reflects account-level behavior rather than the content of individual posts. We randomly sample 1,000 labeled posts, balanced across these nine categories, for the same duration as our firehose collection.

Safe Posts. We collect safe posts from verified organizational accounts on Bluesky. Account collection followed two strategies: (i) we manually curated 47 accounts across news media, academic and research institutions, government and intergovernmental organizations, and NGOs, selected based on institutional accountability and domain-verified handles or Bluesky-issued verification badges; and (ii) we identified 1,003 accounts from 15 curated Bluesky starter packs spanning science communication, AI and ethics research, healthcare, and related domains. For each account, posts were retrieved via `com.atproto.repo.listRecords` and filtered to remove any post carrying a BMS moderation label as well as quote posts, yielding a pool of 844,344 posts from 194 organizational accounts. We randomly sample 1,000 posts from this pool, balanced across five organizational categories: news media, science and technology, academic, government, and NGO.

Near-moderated Posts. The Near-moderated subset is designed to study potential false negatives from the deployed moderation system and evaluate how VLMs handle content that is semantically similar to previously moderated posts but was not flagged by the platform. We curate a subset of 40M posts drawn randomly from the March–

June 2025 firehose window (383.2M posts total), restricted to text and single-image posts. For each post in the 40M subset, we compute multimodal embeddings using Qwen3-VL-Embedding-2B (Li et al., 2026)¹. Each post is encoded as a multimodal instruction, combining available text and a single image into a 2048-dimensional vector. All embeddings are normalized and inserted sequentially into a `faiss.IndexFlatIP` index.

We then query this index using the Moderated Posts posts ($k=1000$ candidates per query) and, for each labeled post, select the highest-ranked neighbor in the firehose index that carries no BMS label, thus yielding 1,000 semantically similar but unmoderated posts. Embedding-based retrieval makes semantic search feasible at this scale, but it is only one possible strategy for identifying potential false negatives on a live platform. Alternative retrieval or sampling approaches may surface different candidate posts. Analyzing how VLMs capture such potential harms is left for future work.

Human Annotation Process. Our annotation procedure strictly followed the official Bluesky Moderation Service (BMS) label definitions, which served as the sole basis for annotation rather than annotator intuition. A post was labeled *Unsafe* only if it satisfied the criteria of a defined moderation category; otherwise, it was labeled *Safe*. Safe content therefore included everyday posts, news, humor, non-targeted strong language, fictional violence, journalism, and clearly labeled parody.

We first conducted a 100-instance pilot in which two annotators independently labeled posts according to the official BMS definitions. They then jointly reviewed all disagreements to identify ambiguous cases, establish explicit decision rules for edge cases, and develop a shared annotation codebook that standardized labeling across harm categories. Each post was evaluated atomically and in isolation, without reply context, external links, or other platform metadata. Text and images were assessed jointly, and a post was labeled *Unsafe* if either modality independently satisfied an unsafe-category definition. For more subjective categories, particularly sexual, rude, intolerance, threat, and graphic-media, we supplemented the official definitions with explicit decision rules covering cases such as artistic nudity, figurative violent language, and political criticism.

¹<https://huggingface.co/Qwen/Qwen3-VL-Embedding-2B>

Using the finalized annotation guidelines, two annotators independently labeled the full dataset. For the Random Posts subset, they initially disagreed on 31 posts. Joint discussion resolved 21 of these cases and further refined the guidelines, while the remaining 10 cases were adjudicated by a third annotator. The refined guidelines were then applied to the remaining subsets. The Near-moderated Posts and Moderated Posts subsets produced 120 and 163 disagreements, respectively, all of which were resolved by a third annotator, whereas the Safe Posts subset had complete agreement. Most disagreements involved rude /intolerance /threat content, reflecting the greater subjectivity of these categories and Bluesky’s own reliance on human moderation for such judgments.

Notes on Data Usage. The primary purpose of the data provided as part of MODERATIONBENCH is to *benchmark and analyze* content moderation models. If later used for training or fine-tuning, downstream methods would need to account for both shifts in online content and adaptations in platform policies and labels. One promising direction is to move from a static benchmark toward streaming data collection, combined with continual adaptation to evolving content and policies.

B Bluesky Automod and Hive AI

Bluesky’s automated content moderation uses two components: *Hive AI*, a commercial multi-head vision classifier, and *automod*, Bluesky’s open-source rule engine that converts Hive’s raw scores into actionable labels. When a post containing an image (individual frames in case of video) is submitted, Bluesky submits it to the Hive API. Hive AI’s visual moderation API returns a flat list of 128 class-score pairs organised into 54 model heads spanning five different domains: sexual content (26 heads, 59 classes), violence and gore (10 heads, 29 classes), drugs and vices (6 heads, 15 classes), hate imagery (5 heads, 10 classes), and miscellaneous image attributes (7 heads, 15 classes), as documented in the Hive Visual Moderation API (The Hive, 2026). Automod applies hard-coded threshold rules over Hive’s output scores across the different classes to produce Bluesky labels. Each rule checks a specific Hive class against a fixed threshold: for example, $\text{yes_self_harm} \geq 0.96$ triggers self-harm, and $\text{yes_sexual_activity} \geq 0.90$ triggers porn. Automod’s rules are hard-coded:

with a fixed (and potentially arbitrary) threshold and a fixed set of heads. This rigidity can make such a system brittle: a post whose Hive scores sit just under a fixed threshold (or whose harmful content simply isn't covered by any of the heads used in Automod) can slip through unlabeled, regardless of how clear the violation is to a human reviewer.

C Instruction-Driven Moderation Setup

C.1 Gathering Moderation Instructions: Bluesky

Label Descriptions For Bluesky, the *label descriptions* are obtained from the Bluesky Moderation Service (Bluesky Moderation Service) profile. The profile defines the specific labels it uses to categorize harmful content on the platform. Moreover, for most labels, it also provides succinct descriptions. For more sufficient definitions of some labels like porn, sexual, nudity, graphic-media, we also leverage Bluesky's advanced guide² that contains some keywords related to these labels. Finally, we also look at Bluesky's automod code, the open-source ruleset it uses to map Hive API's content labels to specific platform labels, to find code comments related to specific labels (porn, sexual, nudity). Using these different sources, we create concise single-sentence descriptions for the specific labels mentioned. These are shown in Table 7.

Community Guidelines Bluesky provides high-level principles and rationale for moderation in its Community Guidelines (Bluesky, 2025). In its guidelines, it highlights high-level principles (Safety First, Respect Others, Be Authentic, Follow the Rules) alongside detailed notation of what is and is not allowed on the platform. We provide the community guidelines without alteration in the model prompt when using *guidelines*.

Detailed Rules For the labels that Bluesky moderates automatically, it leverages Hive's API, whose Visual Moderation returns several harmful content category scores. Bluesky maps these different content scores to labels via concrete rules using thresholds in its open-source automod code. The content classes of Hive that are considered for each label are as follows.

- porn: yes_sexual_activity **OR**
 animal_genitalia_and_human **OR**

²<https://docs.bsky.app/docs/advanced-guides/moderation#global-label-values>

Name	Description	Sources
porn	Contains imagery with explicit sexual content, including depictions of sexual activity, full-frontal nudity, or any material that is overtly sexual or adult in nature.	Moderation service, Advanced guides, Automod comments
sexual	Contains sexually suggestive content that, while not explicitly depicting sexual activity or full nudity, implies sexual intent or provocation through poses, context, or partial nudity.	Moderation service, Advanced guides, Automod comments
sexual-figurative	Contains sexually suggestive cartoons, e.g., art with explicit or suggestive sexual themes, including provocative imagery or partial nudity.	Moderation service
self-harm	Promotes self-harm, including graphic images, glorifying discussions, or triggering stories.	Moderation service
nudity	Contains imagery with non-sexual depictions of the human body in full or partial nudity, including artistic, photographic, or editorial nudity that lacks any sexual intent or suggestive context.	Moderation service, Advanced guides, Automod comments
intolerant	Contains discrimination against protected groups.	Moderation service
graphic-media	Contains imagery that is explicit or potentially disturbing, especially regarding violence or gore.	Moderation service, Advanced guides
rude	Contains rude or impolite content, including crude language and disrespectful comments, without constructive purpose.	Moderation service
threat	Promotes violence or harm towards others, including threats, incitement, or advocacy of harm.	Moderation service

Table 7: Bluesky moderation labels with descriptions.

```
yes_realistic_nsfw;       general_nsfw
AND            animated_animal_genitalia;
yes_undressed                               AND
yes_sexual_activity
```

- sexual: yes_sexual_intent **OR**
yes_sex_toy; yes_undressed **AND**
yes_sex_toy; yes_male_underwear **OR**
yes_female_underwear
- nudity: yes_male_nudity **OR**
yes_female_nudity **OR** yes_undressed
- graphic-media: very_bloody **OR**
human_corpse **OR** hanging
- self-harm: yes_self_harm

Importantly, for each of these content classes, Hive documents which aspects are considered in the scope³. We document these points and then feed the rules alongside these scope points to Claude Sonnet, prompting it to design policy points. For human-applied labels like intolerance, rude, and threat, there is no detailed scope documented. Hence, we additionally consider Bluesky's Transparency Report (Bluesky, 2026) to incorporate certain relevant phrases in the details aspect. Table 3

³<https://docs.thehive.ai/docs/visual-content-moderation>

shows the platform policy summary. These details are fed into the prompt.

C.2 Moderation Instructions for Prompt

The first level of moderation instructions informs the VLM *the core aspect of moderation*, the *What* that needs to be moderated. Hence, we provide **Label Descriptions** in the prompt, which are provided under the **LABELING POLICY DETAILS** section of the prompt policy.

Label Descriptions

LABELING POLICY DETAILS

S1 – porn: The social media post shall not contain imagery with explicit sexual content, including depictions of sexual activity, full-frontal nudity, or any material that is overtly sexual or adult in nature.

S2 – sexual: The social media post shall not contain sexually suggestive content that, while not explicitly depicting sexual activity or full nudity, implies sexual intent or provocation through poses, context, or partial nudity.

S3 – sexual-figurative: The social media post shall not contain sexually suggestive cartoons, e.g., art with explicit or suggestive sexual themes, including provocative imagery or partial nudity.

S4 – self-harm: The social media post shall not promote self-harm, including graphic images, glorifying discussions, or triggering stories.

S5 – nudity: The social media post shall not contain imagery with non-sexual depictions of the human body in full or partial nudity, including artistic, photographic, or editorial nudity that lacks any sexual intent or suggestive context.

S6 – intolerant: The social media post shall not contain discrimination against protected groups.

S7 – graphic-media: The social media post shall not contain imagery that is explicit or potentially disturbing, especially regarding violence or gore.

S8 – rude: The social media post shall not contain rude or impolite content, including crude language and disrespectful comments, without constructive purpose.

S9 – threat: The social media post shall not promote violence or harm towards others, including threats, incitement, or advocacy of harm.

S10 – other-unsafe: The social media post shall not contain unsafe or problematic content that violates the moderation policy but does not fit the labels above.

S0 – no-moderation: The social media post does not need to be moderated.

Next, we provide the *Why* of moderation, incorporating Bluesky’s Community Guidelines. These give the VLMs a background on the **rationale for moderation**. Note that we only format the guidelines into markdown and perform no other major modifications from the original document. This detail is provided in the **COMMUNITY GUIDELINES** section of the prompt policy.

Community Guidelines

These Guidelines aim to promote a safe and enjoyable experience for everyone on the platform. Moderation is grounded in respect for human rights and fundamental freedoms, while recognizing that laws must be followed across jurisdictions.

Our Principles: (1) **Safety First:** Content showing or promoting violence, harm, exploitation, or criminal activity is not allowed. (2) **Respect Others:** Harassment, bullying, hate speech, or discrimination are not allowed. (3) **Be Authentic:** Content intended to misrepresent, defraud, or deceive is not allowed. (4) **Follow the Rules:** Content violating applicable laws or platform policies is not allowed.

1. Safety First
Public Safety. Posts should not coordinate or recruit for criminal organizations, provide instructions for criminal acts, or share violent content for harmful purposes.

Respectful Discourse. Posts should not threaten others, promote or incite

violence, or share graphic violent content to shock or intimidate. Exceptions: professional combat sports, martial arts, and violence in clearly fictional or artistic contexts.

Child Safety. Posts should not create or share content that sexualizes or exploits minors, engage in grooming behavior, or share personal information about minors.

Adult Content. Consensual adult sexual content is allowed when appropriately labeled. Non-consensual content, content involving realistic risk of death, and technology-facilitated harassment are not allowed.

Mental Health & Wellbeing. Posts should not promote self-harm, suicide, eating disorders, dangerous stunts, or abuse of controlled substances.

Privacy Protection. Posts should not share addresses, contact information, financial or medical data, private communications, or real-time location data without authorization.

Animal Safety. Posts should not depict sexual content involving animals or animal abuse, torture, or fighting. Hunting, fishing, and other legal wildlife activities are permitted.

2. Respect Others

Anti-Discrimination. Posts should not attack, harass, or incite hatred against individuals or groups based on protected characteristics such as age, disability, ethnicity, gender identity, race, religion, sex, or sexual orientation.

Anti-Harassment. One should not stalk, persistently target, or create malicious content to humiliate individuals, abuse platform features for harassment, or engage in coordinated harassment campaigns.

3. Be Authentic

Trust & Transparency. One should not send spam, promote financial scams or phishing, artificially inflate engagement metrics, or post undisclosed commercial content.

Account Authenticity. One should not impersonate others, engage in identity churning, falsify verification status, or bypass age requirements. Clearly labeled parody, satire, fan, or fictional accounts are permitted.

Information Integrity. One should not share false information likely to cause immediate real-world harm, or interfere with democratic processes such as voting.

4. Follow the Rules

Regulated Goods & Services. The platform should not be used to sell or facilitate transactions for controlled substances, weapons, stolen goods, or other restricted items.

Intellectual Property & Copyright. One should not infringe copyrights, remove attribution, violate trademarks, or share unauthorized streams or downloads.

Site Security. One should not attempt to compromise, exploit, or disrupt the platform’s systems, APIs, or infrastructure.

Repeated Violations & Ban Evasion. One should not create new accounts or use alternative methods to evade bans or suspensions.

5. Protected Expression

The following content is welcome when appropriately labeled: (1) **Journalism, Analysis, Education, and Advocacy:** Factual reporting, academic research, anti-violence advocacy, and safety campaigns. (2) **Support & Recovery:** Personal recovery experiences, survivor stories, mental health resources, and crisis prevention information. (3) **Transparency and Public Information:** Publicly available official records related to government transparency and public officials.

Finally, we have the **Detailed Rules** that augment each label, especially the automated ones, with detailed aspects that fall in scope based on the Hive API documentation.

Labeling Policy Details with Rules

S1 – porn: The social media post shall not contain imagery with explicit sexual content, including depictions of sexual activity, full-frontal nudity, or any material that is overtly sexual or adult in nature.

Further Details on Scope: Depictions of sexual activity: Sexual intercourse, masturbation, or oral sex involving genitals, anus, or breasts; any explicit direct touching of genitals; kissing where at least one person is also nude; semen or vaginal fluids on faces or other body parts; sex toys where it is clearly penetrating the mouth, anus, or genitals, or being used on someone; bondage explicitly presented in a sexual context. **Full or prominent nudity:** Genitals, buttocks, anus, or female nipples shown directly or clearly visible through transparent, sheer, or mesh clothing; full nudity even where genitals or nipples are not directly visible (e.g., side-on view of a fully nude person); vaginal fluids or semen depicted in an image; textbook-style or illustrative diagrams of genitalia when presented in a sexual or pornographic context; photorealistic nudity or sex acts, including photorealistic representations or photographs of real subjects; animated pornography showing nudity and sexual acts; non-artistic drawings (e.g., doodles, graffiti) depicting nudity, genitalia, or breasts. **Animal or humanoid sexual content:** A human touching, licking, or penetrating animal genitalia, or vice versa; animals or animal-like creatures (including dragons, aliens, or fantasy characters) with distinguishable genitals, or engaged in sexual kissing, licking, or penetration; humanoid creatures showing clear and prominent animal genitalia; nude animated humans with animal-like features

(tails, fur, animal ears) explicitly engaged in sexual activity. **Undressed people in sexual activity:** Imagery depicting a naked or undressed person (genitals directly observed, occluded by pose, hands, objects, or digital overlay such as emojis or stickers) in combination with clear depictions of any sexual activity as described above.

S2 – sexual: The social media post shall not contain sexually suggestive content that, while not explicitly depicting sexual activity or full nudity, implies sexual intent or provocation through poses, context, or partial nudity.

Further Details on Scope: Implied or partially obscured sexual activity: Clear sexual activity that has been blurred, pixelated, covered by stickers, banners, emojis, or other overlays, or pushed to the background or edge of the frame; images clearly intended to imply sexual activity is occurring, even if not explicitly shown; diagrams or illustrations of sexual positions, even without visible nudity; face close-ups in the context of pornographic or sexual activity imagery; people in sexual positions or poses, even without nudity present; slight but intentional nudity (e.g., flashing, strip tease, the act of removing clothing). **Imagery showing sexual objects that are not explicitly being used on someone:** Dildos, vibrators, sex dolls, fleshlights, butt plugs or beads; harnesses, restraints, or equipment intended for bondage; any sex toy or similar object visibly present in the image. **Underwear imagery:** Men visibly wearing boxers, briefs, boxer briefs, jockstraps, or thongs, including underwear visible above low-worn pants or through unzipped clothing; women visibly wearing underwear, panties, thongs, bras, sports bras, or lingerie without covering clothing, or underwear visible under a dress, skirt, or through transparent clothing; women in the process of removing underwear; clothing or objects not being worn but covering genitals in a manner similar to underwear. **Undressed persons with visible sex toys without explicit sexual activities:** Imagery of an undressed or naked person combined with any visible sex toy, even if no explicit sexual activity is depicted.

S3 – sexual-figurative: The social media post shall not contain sexually suggestive cartoons, e.g., art with explicit or suggestive sexual themes, including provocative imagery or partial nudity.

Further Details on Scope: Cartoons or art with suggestive sexual themes: Illustrated, animated, or cartoon depictions of sexual themes, provocative poses, or partial nudity; animated human characters with animal-like features (fur, tails, animal ears) showing nudity but not engaged in sexual activity.

S4 – self-harm: The social media post shall not promote self-harm, including graphic images, glorifying discussions, or triggering stories.

Further Details on Scope: Visual depictions: Images (photographic, animated, illustrated, or artistic) of someone cutting or burning themselves; images of self-inflicted cuts or burn scars (identifiable by location, number, dimensions, direction, or hesitation marks); a person pointing a gun to their own head or chest; a person holding knives, razor blades, fire, or hot objects against their body; depictions of religious self-harm such as self-flagellation or self-immolation.

S5 – nudity: The social media post shall not contain imagery with non-sexual depictions of the human body in full or partial nudity, including artistic, photographic, or editorial nudity that lacks any sexual intent or suggestive context.

Further Details on Scope: Non-sexual Male and Transgender Nudity: Visible penis and/or testicles; male buttocks or anus visible without clothing; penis or testicles visible through see-through, sheer, or mesh clothing, or sticking out of underwear or pants; pubic hair visible around the male crotch region, even if genitals are not shown or covered. **Non-sexual Female and Transgender Nudity:** Exposed female genitalia or anus; visible female nipples or areola; bare buttocks including from side angles; any of the above visible through see-through, sheer, or mesh clothing; pubic hair visible around the female crotch region, even if genitals are not shown. **Non-sexual General Undressed:** Images of a naked or undressed person where genitals, breasts, or buttocks are directly shown or are not visible due to the subject's pose or the angle; body parts covered by hands, unworn clothing, or other objects; body parts covered, blurred, or occluded by digital overlays (emojis, stickers, censure bars, text); female nipples covered by stickers or body paint.

S6 – intolerant: The social media post shall not contain discrimination against protected groups.

Important Notes: Careful attention to cultural context, language nuances, and intent is essential to ensure correctly distinguishing hate speech from vigorous criticism, satire, or commentary. Vigorous debate, political criticism, and commentary on ideas, even harsh or provocative, are allowed. However, in these contexts, crossing into attacks on people based on protected identity should be labeled.

S7 – graphic-media: The social media post shall not contain imagery that is explicit or potentially disturbing, especially regarding violence or gore.

Further Details on Scope: Graphic imagery of violence and gore: Photographs showing substantial amounts of blood, major wounds that are actively bleeding, or severe gore; gunshot wounds, stab wounds, or deep cuts; injuries resulting in loss of limbs, fingers, or similar severe bodily damage; animal attacks or bites with visible severe injury; profuse bloody noses (when extreme). **Graphic imagery of death:** Photographs of a dead human body, including motionless bodies with evidence of potentially fatal injury; bodies clearly identifiable as dead based on physical signs (color, lividity, decomposition), even if no injuries are visible; bodies clearly identifiable as dead based on contextual factors (e.g., in a casket, in a morgue); autopsy photographs; any of the above as depicted by actors using makeup and effects in a film or TV context; photographs, art, animations, or illustrations of hangings or hanging bodies.

S8 – rude: The social media post shall not contain rude or impolite, including crude language and disrespectful comments, without constructive purpose.

Important Notes: Content that is harsh but has substantive criticism, disagreement, or debate without an intent to attack is allowed and should not be labeled. Content containing impolite or crude language that is not directed as an attack against a specific person or group, but is instead used as exaggeration, exasperation, excitement, or a figure of speech, e.g., when directed at a situation, object, or experience, is allowed and should not be labeled.

S9 – threat: The social media post shall not promote violence or harm towards others, including threats, incitement, or advocacy of harm.

Important Notes: Content that is not a threat but a hyperbolic expression, dark humor, or fictional expression with no clear threatening intent should not be flagged.

S10 – other-unsafe: The social media post shall not contain some other unsafe or problematic content that violates the moderation policy but does not fit into the other moderation labels defined above.

S0 – no-moderation: The social media post does not need to be moderated.

C.3 Final Prompt Structure

Our final prompt considers these different policy parts, combining them based on which aspects we incorporate. For instance, if we include only the *What* and *How*, we only incorporate the *Label descriptions* with *Community guidelines*, while not including the *Detailed rules*. The prompt structure is as follows.

Moderation Prompt

System Prompt: You are an expert content moderator for a social media platform. Your task is to determine whether a given social media post requires moderation and what labels need to be applied based on the safety policy provided to you. The safety policy begins with a {description of the platform's community guidelines, which should be used to determine whether the post requires moderation}. Next, it contains the labeling policy, which should be used to decide the relevant labels to apply if moderation is needed. Then, you will be given the particular social media post and its contents (text and visual) that need to be analyzed. Finally, you will be provided the specific JSON format in which your decision must be returned. Examine all provided content (text and visual) {alongside the community guidelines} and labeling policy before making a decision, and apply only the labels defined under the labeling policy.

{COMMUNITY GUIDELINES}

{If using rationale, provide information given in Community Guidelines}

LABELING POLICY DETAILS

{If not using details, provide information given in Label Descriptions.}

{Else, provide the full Labeling Policy Details with Rules. }

Social Media Post to be Categorized: Text: [post text].

Visual: [post image].

Analysis and Output Instructions

Analysis: Carefully examine all post content against the labeling policy details to determine if the post does not need moderation (S0) or requires labeling for moderation (using labels except S0 from the Labeling Policy Details). Even if some content types are allowed on the platform, they might need to be moderated and appropriately labeled for safety and appropriate viewing.

PREDICTED_CATEGORY_ID: Identify the single best matching label for moderation. Multiple labels are not allowed. If choosing no moderation needed (S0), no other moderation label should be chosen. Only use S10 as a last resort when the content needs moderation but does not fall into any other policy label. If some other moderation label generally fits the content, prefer that over S10.

CONFIDENCE_SCORE: Rate your confidence in the prediction on a 1–5 Likert scale: 1 = Not at all confident; 2 = Somewhat low confidence; 3 = Medium confidence; 4 = Somewhat high confidence; 5 = Very high confidence.

Required Format: Return your decision as a JSON object with exactly the following fields. Do not include any additional text as output outside the JSON.

```
{
  "PREDICTED_CATEGORY_ID": "Sx",
  "CONFIDENCE_SCORE": likert_scale_1_to_5
}
```

Note that the first paragraph of the prompt is provided as a system prompt. This prompt minimally changes when the guidelines are not provided. The **COMMUNITY GUIDELINES** section is filled when we wish to provide the platform guidelines alongside the policy. Similarly, when detailed rules are to be fed, the *Scope* and *Notes* of each label is used to fill up the prompt.

C.4 Prompt for Model Judgments

To obtain the judgments from VLMs regarding their moderation decisions on data inputs, we leverage multi-turn prompting. Specifically, as another turn in the chat, we prompt the models, conditioned on the input policy and the model’s moderation decision, (i) *a brief explanation* of how the model judged the input content and (ii) *specific, verbatim policy quotes* that the model considered relevant for its final prediction. The following prompt is sent as a further turn in the conversation with the VLM, where the model has read the policy and the input post to give its moderation decision JSON.

Justification Prompt (Explanation & Policy Quotes)

EXPLANATION: Provide a concise 2–3 sentence explanation of your final decision. Note:
First, briefly describe what specific element of the post (text, image, or both) triggered the decision.
Then, state the policy rule or criterion it violates, using the language of the policy.
If the post requires no moderation (S0), briefly state what the content is and why it does not meet the threshold for any category.
Do not describe your reasoning process or alternatives you considered. State only the justification for your final conclusion.

POLICY_QUOTES: List exact verbatim excerpts from the policy text that are directly attributed to your final labeling decision. Each excerpt must be copied exactly as it appears in the policy, enclosed in quotes ("..."). This applies even when predicting no moderation (S0). For S0, quote specific text from the policy and community guidelines explaining why the content is allowed, not the S0 label definition itself.

Provide your justification as a JSON object with exactly this structure:

```
{
  "POLICY_QUOTES": ["verbatim excerpt from policy", "..."],
  "EXPLANATION": "2-3 sentences justifying your decision"
}
```

D Example-Driven Moderation Setup

D.1 Example Curation

For generating prototypical and contextual examples, we use Qwen3-VL-Embedding-2B (Li et al., 2026), which is an encoder model. In the prototypical setting, for each label (as well as safe posts) we first calculate the mean embedding of each label. Then we find the closest posts to that mean embedding. We create a FAISS index (Johnson et al., 2019) of the label posts to enhance the speed of finding the closest posts. Our metric for this part is cosine similarity. In the Contextual setting, we get the 10 closest posts per label from all the moderated posts as well as safe curated posts for each query post.

Example Posts Data Subset. As mentioned before, safe examples are from the entire curated Safe Posts set of labels we collected (Section 3). The labeled posts are from the label stream of Bluesky that we gathered. We ensure that these post subsets do not have *any overlap* with the specific posts we analyze as part of MODERATIONBENCH

by not considering post IDs that already exist in the analysis datasets.

D.2 Final Prompt Structure

This setting contains many posts with multiple images, which can increase the prompt length, and it can be larger than the context window. In order to mitigate this problem, we decided to only keep the policy labels (What). Here is the system prompt as well as the user prompt for this experiment.

System Prompt

You are an expert content moderator for a social media platform. Your task is to determine whether a given social media post requires moderation and what labels need to be applied based on the safety policy provided to you. The safety policy contains the labeling policy, which should be used to decide the relevant labels to apply if moderation is needed. **After that, you will be given some example posts and their moderation label decisions.** Then, you will be given the particular social media post and its contents (text and visual) that need to be analyzed. Finally, you will be provided the specific JSON format in which your decision must be returned. Examine all provided content (text and visual) alongside the safety policy before making a decision, and apply only the labels defined under the labeling policy

Moderation Prompt

System Prompt

LABELING POLICY DETAILS

EXAMPLES
Below are example Social Media Posts with texts and/or images and their corresponding moderation labels.

Social Media Post to be Categorized:
Text: [post text].
Visual: [post image].

ANALYSIS AND OUTPUT INSTRUCTIONS

In example-driven settings, for open-weight models, providing 10 examples per label across all 9 unsafe labels plus the safe category would exceed model context limits and exhaust GPU memory. To address this, we decompose classification into three independent group-level calls per post, each covering one thematic label group: **sexual** (porn, sexual, figurative, nudity), **graphic** (graphic-media, self-harm), **hostile**(intolerance, rude, threat). Each call exposes only the policy labels belonging to that group alongside the safe label (S0), and sees $K = 10$ labeled precedents per unsafe label plus $K = 10$ safe contrast examples. The final label is determined by aggregating the three group-level votes. Here is the prompt for this experiment.

Moderation Prompt (Group Call g) for example-driven

System Prompt

LABELING POLICY DETAILS
Policy definitions shown only for the labels in group g and S0:
 [label id]: [label name] — The social media post shall not [policy description].
 :
 :
 S0: no-moderation — The social media post does not need to be moderated.

EXAMPLES
 Below are example Social Media Posts with texts and/or images and their corresponding moderation labels.

Social Media Post to be Categorized:
 Text: [post text].
 Visual: [post image].

ANALYSIS AND OUTPUT INSTRUCTIONS
 Choose exactly one of: [group g label ids] | S0 | other
 other means the post has content issues but does *not* match any label in group g (i.e. it better fits a label from another group).
 Return your decision as a JSON object:

```
{
  "PREDICTED_CATEGORY_ID": "<Si where i in group g | S0 | other>"
  "CONFIDENCE_SCORE": likert_scale_1_to_5
}
```

The three group calls produce votes $\hat{y}_{sexual}$, $\hat{y}_{graphic}$, $\hat{y}_{hostile}$. The final label is determined by the following rule: if any group returns an unsafe label (i.e., not S0 or other), the unsafe label with the highest severity among those votes is selected (priority order $S1 \prec S2 \prec \dots \prec S9$); if no group votes unsafe but at least one returns other, the post is flagged as (S10).

E Practical Details

E.1 Models Benchmarked

Instruct Models. gemma3-27b (Kamath et al., 2025), qwen3-vl-32b (Bai et al., 2025), mistral3.2-24b (Mistral AI, 2025), llava-ov-72b (Li et al., 2024), llama4-scout (Meta AI, 2025).

Reasoning Models. gemma4-31b (Google DeepMind, 2026), qwen3-vl-32b-thinking (Bai et al., 2025), qwen3.5-27b (Qwen Team, 2026), internvl3.5-38b (Wang et al., 2025a), magistral-small11.2-24b (Rastogi et al., 2025).

Frontier Models. We also evaluate two frontier models, gemini3.5-flash and gpt5.6-terra, using their default *medium* reasoning level.

E.2 Details on Safety Models

Llama-Guard-4-12B. This model was fine-tuned on its specific harm taxonomy⁴. Hence, any query instance passed to the model at the inference stage is *automatically evaluated* based on its native

⁴<https://developer.meta.com/ai/docs/model-cards-and-prompt-formats/llama-guard-4/>

policy (termed Own in the main paper). However, by leveraging vllm for inference, it is possible to override the existing policy in the prompt to a user-defined policy by passing a user-defined category and definition mapping through categories under chat_template_kwargs of LLM.chat() of vllm. So, we use this pipeline to override the inference call with the Bluesky policy with Labels+Details.

Shieldstral-1.0-3B. This recently released AI safety model was fine-tuned to remain *flexible to changing taxonomies and policies*, allowing it to natively operate with different policies at inference time. To support this flexibility, shieldstral frames moderation as a question-answering task using an Instruction, Query, Document prompt structure. In our setting, the full policy is provided as the Instruction, a moderation question as the Query, and the multimodal social media post as the Document. To operationalize the Bluesky policy, we make *ten inference calls*, each asking whether the post should be flagged under one of the ten harm labels (porn to other-unsafe) in our policy, while providing the full policy as the Instruction in each call. Using the model’s *default threshold of 0.5*, we predict Safe: no-moderation if all label scores fall below the threshold; otherwise, we predict the harm label with the highest score.

E.3 Practical Setup

Inference Details VLM inference is performed using vllm and transformers (specific version details provided below). The specific inference parameters used are as follows: max_model_len: Varies between models based on token usage. Set mostly to 32768, while for mistral and magistral it is set to 81920 since these models use more tokens for encoding images.

- max_new_tokens: Set to 8192 to allow sufficient reasoning for thinking models.
- temperature: Set to 0 to ensure deterministic results for our study.
- top_p, top_k: Set to 1.
- thinking_token_budget: Set to 3000 tokens to avoid unending reasoning streams. This number was selected by looking at the average reasoning length on a separate data subset.
- repetition_penalty: Set to 1.2 to avoid degenerate reasoning. This number was also selected by analyzing results on a separate data subset.

Implementation Details The implementation leverages the following packages and versions:

torch: 2.10.0+cu128, transformers: 5.6.2, vllm: 0.19.1, mistral-common: 1.11.0.

The inference was performed on machines with a single H200 GPU for most models (for LLaVa-OV-72B, we used 2 H200 GPUs) and 200GB of memory, setting a batch size of 50. For each run for a model and setup combination on a particular dataset, inference is completed within 30 minutes for instruction-driven approaches and 180 minutes for example-driven ones. Thinking models required more time owing to the extensive reasoning the models perform before giving output.

Since the example-driven setting requires multiple calls per test instance and incurs larger GPU memory usage per example compared to the instruction-only setting, we use a batch size of 10. Moreover, we did not evaluate llava-ov-72b and internv13.5-38b in the example-driven setting. Both of these models context window is 32k and they have a high per-image token cost. This prevented us from providing a comparable number of in-context examples to those used with the other models, so we did not consider these models.

F Instruction-Driven Moderation

F.1 Moderation Effectiveness

We present the variation in F_1 scores across models and instruction levels on Random Posts, Moderated Posts, and Near-moderated Posts in Fig. 7. Note that F_1 scores are not applicable for Safe Posts, as human annotators identified no unsafe content in that subset.

Increasing policy instruction granularity consistently improves VLM alignment with human moderation judgments. Across all data subsets of MODERATIONBENCH, models exhibit broadly similar trends: F_1 scores generally improve as instruction detail increases, with the most pronounced gains observed when detailed rules are provided. The trends previously reported for the select models on Random Posts generalize across all other models. A similar pattern holds for Near-moderated Posts, where detailed rules again yield F_1 improvements, though the magnitude of gains is smaller than on Random Posts. On Moderated Posts, F_1 scores are already high across instruction levels, with only minimal variation as policy detail increases — suggesting that models can reliably identify clearly moderated content even under sparser instructions. Notably, on Random Posts and Near-moderated Posts, richer instructions

Figure 7: F_1 score of models for **instruction-driven moderation** as policy instructions vary. Bluesky does not flag any content in Safe Posts, leading to **zero** F_1 .

further widen the gap between VLM F_1 scores and Bluesky’s baseline moderation system relative to human annotations.

Open models are competitive with frontier models. Our results across all datasets show that open models remain competitive when compared to the frontier models. Interestingly, from the results in the main paper and those here, we see that many open models can outperform gpt5.6, whereas gemini3.5 is marginally better than the best open models. However, since frontier models can only be accessed through APIs, they have their own usage policies. Given that content moderation can have *very sensitive and harmful content* sent to the models for processing, we observe that in the instruction-driven paradigm, there can be rare occasions of the **frontier models refusing to process and answer**. For instance, for gemini, while some setups can see refusal rates of 0.1–0.2%, this can increase to 0.7% on Moderated Posts. In contrast, **none of the open models** refuse to answer the moderation requests, showing higher steerability.

Overall, these results reinforce that detailed, rule-grounded policy specifications are an effective lever for improving VLM prediction quality — in some cases surpassing Bluesky’s existing auto-

mated moderation system when evaluated against human judgments.

F.2 Flagging Rates

We show additional results regarding model flagging on content and consistency in its predictions.

Fig. 8 presents the flagging rates of all models across the different instruction-driven moderation policy detail levels on each data component of MODERATIONBENCH. The trends observed for the select models on Random Posts in the main paper largely generalize: *VLMs become more conservative in their flagging and approach human annotator levels as policy detail increases.*

On Random Posts, rationales reduce flagging for most models (exceptions: gemma3 and mistral), while detailed rules reduce flagging across all models. Combining rationales with details can slightly raise flagging rates for some models; nevertheless, these rates remain closer to human annotator levels than when only label descriptions are provided.

On Moderated Posts, VLMs successfully flag the majority of content that Bluesky had moderated. Interestingly, human annotators marked several of these instances as safe, suggesting that even platform-level moderation can tend toward over-flagging. Here too, richer policy instructions steer models toward more conservative, human-aligned flagging.

On Safe Posts, VLMs correctly flag little to none of the content, consistent with human annotators who also raised no moderation flags for these posts. For this subset, adding rationales alongside label descriptions can marginally increase flagging in some models; however, providing more detailed rules brings it back down sharply, to 0.5

On Near-moderated Posts, VLMs correctly identify some harmful content, mirroring the behavior of human annotators who likewise flagged a subset of these posts — despite Bluesky’s Moderation Service not flagging any of them. The overarching trend holds: models overflag under sparse label descriptions, while richer instructions through rationales and detailed rules substantially reduce flagging and bring it closer to human annotation levels.

Our results consistently demonstrate that the granularity of policy instructions is a critical lever for calibrating VLM moderation behavior. Across all data subsets, moving from bare label descriptions to detailed, rationale-grounded rules reliably reduces over-flagging and aligns model outputs

more closely with human judgment — underscoring the practical importance of well-specified moderation policies when deploying VLMs in real-world content moderation pipelines.

F.3 Practical Efficiency

To understand the practical efficiency of the *instruction-driven paradigm* across different VLMs, we report (i) the average latency in analyzing each social media post across the different policy detail levels and data modalities in Fig. 9 (text-only, single image-only, text+single-image, multi-image, text+multi-image) and (ii) the latency across the number of images present in the social media post being moderated when the policy granularity in the prompt is set at *What, Why & How* in Fig. 10.

Impact of increased policy details. Fig. 9 shows that increasing the amount of policy information in the prompt has only a modest effect on inference time across all evaluated models. Moving from *Labels* to *Labels+Rationale+Details* increases latency by only a few hundred milliseconds for most VLMs, indicating that richer policy descriptions incur little additional computational overhead relative to the cost of model inference itself. This trend is particularly evident for the non-thinking models (qwen3v1 and mistral3), where the latency differences between prompt variants are almost negligible, while the thinking models exhibit a slightly larger but still moderate increase.

Impact of model type. As illustrated in Fig. 9, the dominant factor affecting efficiency is the underlying model architecture. The non-thinking models (qwen3v1 and mistral3) consistently provide the fastest inference, typically requiring less than one second even for multimodal posts. Among the thinking models, gemma4 is consistently more efficient than qwen3.5, while the reasoning-oriented models qwen3v1-th and magistral incur the highest latency. Overall, the choice of model has a substantially larger impact on inference time than the amount of policy information included in the prompt. API-based models’ timing is inconsistent owing to additional latency coming from task scheduling and transmission of data.

Impact of the post’s multimodality. Fig. 10 shows that inference latency increases as posts contain more images under the most detailed policy setting (*What, Why & How*). The increase is most pronounced for the reasoning-intensive mod-

Figure 8: Flagging rates across all models and policy levels on MODERATIONBENCH for **instruction-driven moderation**. Human annotators labeled all instances in Safe Posts as **safe**, leading to **zero flagging**.

	Labels					Labels+Details					Labels+Rationale					Labels+Rationale+Details

Figure 9: Inference efficiency for **instruction-driven moderation** measured by average processing time per post across models, setups, and modalities. gemini and gpt also suffer from task scheduling on the provider’s side, along with data transmission delays.

Figure 10: Inference efficiency for **instruction-driven** moderation by number of images in posts. gemini and gpt show high variance owing to API requests.

els. For example, qwen3vl-th more than doubles its average processing time when moving from text-only posts to posts containing a single image and approaches four seconds for posts with four images. Similarly, qwen3.5 increases from approximately 1.7 s to over 2.5 s across the same range. In contrast, the non-thinking models exhibit a much gentler increase. qwen3vl remains below 0.5 s even for posts with four images, while llama4 stays below one second throughout. Across most models, the largest increase in latency occurs when visual input is first introduced, whereas each additional image contributes a comparatively smaller overhead. The exception is for the frontier models, where processing multiple images through API calls results in a linear increase in time. Nonetheless, for open models, our results suggest that the computational cost is driven primarily by visual reasoning rather than by the number of images alone.

Usage costs of frontier models. For gpt5.6, providing *Labels* alone incurred \$17 on the entire MODERATIONBENCH. The cost increases to \$17.69 when provided *Labels+Rationale*, \$39.57 when provided *Labels+Details*, and \$62.65 when provided *Labels+Rationale+Details*. The increased cost comes from increased reasoning from the models and the increased input prompt length. In contrast, for gemini3.5, *Labels* setup cost \$26.21, *Labels+Rationale* \$44.76, *Labels+Details* \$48.48, and *Labels+Rationale+Details* \$40.68. Interestingly, for this model, providing the full granularity reduces the cost, stemming from the model requiring to perform less reasoning with all details.

F.4 Moderation Consistency

F.4.1 Intra-Model Flagging Consistency

While flagging rates decrease with more granular instructions, it is important to assess whether

model predictions change substantially as policy prompts are progressively enriched. A high rate of prediction changes would indicate that a model is highly sensitive to prompt structure — though some changes are expected and even desirable, as models incorporate additional context to refine their judgments. Fig. 11 shows instance-level prediction flips across instruction levels for gemma4 and qwen3.5 for Random Posts.

Models are largely consistent in their instance-level flagging predictions across policy detail levels. Specifically, 95% of instances for gemma4 and 96% for qwen3.5 remain stably unflagged or flagged regardless of instruction level. For both models, roughly 1–2% of instances transition from flagged to unflagged upon the introduction of rationales and stay unflagged as detail increases further. Conversely, approximately 1% of instances become flagged when rationales are added, only to revert to unflagged once full details are provided.

These findings confirm that instance-level predictions are largely stable across policy configurations. The modest fraction of cases where judgments shift accounts for the observed differences in aggregate flagging rates across setups — but crucially, these shifts are limited in scope and do not reflect large-scale instability in model behavior.

F.4.2 Intra-Model Decision Consistency

Having confirmed that binary flagging predictions remain largely stable across instruction levels, we now examine whether model predictions are equally consistent at the level of specific label assignments. We visualize label prediction changes as Sankey flows in Fig. 12 for Moderated Posts.

VLM label predictions remain largely consistent across instruction setups. The majority of label assignments are preserved across instruction levels for both models. Where changes do occur, they tend to be concentrated within related label groups: transitions between adult content labels, and among the labels that Bluesky routes through its human moderation flow (intolerance, rude, threat). rude and sexual exhibit the most label-level instability for both models as instruction detail increases. Comparing the two models, gemma4 demonstrates greater label prediction consistency than qwen3.5, with fewer assignment changes at each incremental policy update.

Overall, these results suggest that richer policy instructions do not disrupt model predictions: shifts are largely confined to semantically adjacent labels

(a) gemma4

(b) qwen3.5

Figure 11: Binary prediction (Flagged vs. Unflagged) changes across **instruction-driven moderation** setups.

Figure 12: Label-wise prediction changes across instruction levels on Moderated Posts for **instruction-driven moderation** setups.

rather than representing arbitrary reassignments. These findings indicate that VLMs respond to additional policy detail in a meaningful and structured way and highlight the suitability of instruction-driven content moderation.

F.5 Inter-Model Decision Agreement

Having established that individual VLMs remain largely consistent across instruction levels, we now examine how prediction agreement *across different models* shifts with varying policy instruction setups. Fig. 13 presents pairwise Gwet’s AC1 scores for label predictions across model pairs, where higher values indicate stronger inter-model agreement.

Inter-model agreement varies depending on the nature of the content and the level of policy detail. On Random Posts, models exhibit very high pairwise agreement overall, driven largely by the prevalence of safe content that most models consistently predict as such. Providing detailed rules (Labels+Details) further increases agreement across most model pairs, while adding rationales alone has a comparatively minor effect — yielding either similar or marginally lower agreement. A similar pattern holds for Safe Posts, where near-perfect agreement is maintained across all instruction setups, again reflecting broad consensus on non-harmful content.

For Moderated Posts and Near-moderated Posts, inter-model agreement is generally lower, as models more frequently flag content but diverge in their specific label assignments. On Near-moderated Posts in particular, adding rationales can slightly reduce agreement, whereas incorporating detailed rules tends to recover and improve it.

Across the different data subsets and settings, we observe that gemma4 and qwen3.5 achieve the highest pairwise agreement, indicating that these models generally parse and reason on additional instruction levels similarly to reach similar label predictions. On Moderated Posts and Near-moderated Posts, this model pair maintains ≈ 0.8 and higher agreement scores, indicating very high consensus for most instances.

These results suggest that detailed policy rules serve as a stronger alignment signal than rationales alone, consistently nudging models toward more uniform predictions — particularly on challenging or borderline content. This points to the value of precise, rule-grounded policy specifications not only for calibrating individual model behavior, but

also for fostering greater consensus across a diverse set of VLMs.

F.6 Consistency in Decisions and Judgments

F.6.1 Consistency in Decisions

We additionally show the moderation label decision shifts on Moderated Posts between gemma4–gemma3.5 and also between gemma3.5–gpt5.6. These are shown in Figures 14 and 15, respectively.

From both figures, we clearly see that moderation label decisions remain highly consistent between models. However, for each model pair, we see different systematic decision differences.

For gemma4–gemma3.5, we see shifts in sexual and figurative predictions of gemma4 changing to porn predictions from gemma3.5. We also see a lot of instances of intolerance and threat of gemma4 changing to rude in gemma3.5. At smaller scales, we also see changes in the safety judgment itself. For instance, some intolerance and threat cases from gemma flip to safe in gemma3.5. For gemma3.5–gpt5.6, we see more label flips happening.

F.6.2 Consistency in Judgments

As discussed in the main paper, we plot the overall citation distribution for Moderated Posts between gemma4 and qwen3.5 in Fig. 16. In the figure, we see how both models cite only a few rules from the policy. Especially, many rules from the *Rationale* are not cited or are very infrequently cited. From the *Labels*, the definitions and some of the *Details* are well cited. We additionally plot the distribution for the foundation models in Fig. 18. We see very similar behavior for these models as well, where many policy rules are not cited by models. For instance, 36.7% of rules are never cited by either of the foundation models.

We also analyze the distributions for *decision agreements* on Moderated Posts. From Fig. 17 and 19, we see how the distributions across the models appear to match. This behavior indicates that when moderation decisions align, the judgments the models make also become consistent.

For decision disagreements between gemma3.5 and gpt5.6, we plot the citation distributions in Fig. 20. Similar to the observations made in the

(a) Random Posts

(b) Moderated Posts

(c) Near-moderated Posts

Figure 13: Pairwise model agreement scores (Gwet's AC1) across all models and datasets for **instruction-driven moderation** setups. Agreement for Safe Posts is not shown since all models show perfect agreement owing to near-zero flagging.

Figure 14: Prediction label differences between gemma4 and gemini3.5 on Moderated Posts.

Figure 15: Prediction label differences between gemini3.5 and gpt5.6 on Moderated Posts.

main paper, we see that the distributions diverge significantly in this case. For instance, gpt5.6 cites the porn definition at much higher rates. Similarly, it cites the *Details (Notes)* for rude at much higher rates, while gemini3.5 cites the definition.

G Additional Results on Example-Driven Moderation

In this section, we analyze the impact of giving different examples, such as Random, Prototypical, and Contextual. The experiments in the main paper are expanded here.

G.1 Moderation Effectiveness

Much like different instruction granularities impact VLM predictions in the instruction-driven paradigm, we also observe VLMs’ predictions being affected by different kinds of examples in the

example-driven paradigm. In Sec. 5.2, on Random Posts, we discussed that VLMs perform best with prototypical examples, with even weaker models such as qwen3-vl, mistral3, and magistral outperforming BMS, while performance diminishes greatly with contextual examples. Aggregated across all ten models, the false-positive rate on Random Posts nearly doubles from Prototypical to Contextual (13.6% vs. 28.7%, vs. 17.2% for Random examples), confirming that Prototypical is not merely the best-performing setup but also the most conservative one. This over-flagging is heavily concentrated in a single category: rude alone accounts for 2470 of the 5707 total false positives across all models and settings (43%), and its share grows sharply under contextual prompting—1247 rude false positives under Contextual versus 523 under Prototypical, more than double. The pattern is most extreme for weaker models: llama4 and mistral3 misclassify safe content as rude in 291 and 198 cases respectively under Contextual (up from 150 and 59 under Prototypical), together accounting for over a third of all Contextual rude false positives. A secondary effect is visible for sexual/figurative: contextual examples also inflate false positives in these categories specifically (e.g., gemma3 jumps from 30 sexual false positives under Prototypical to 176 under Contextual), suggesting the in-context exemplars used for Contextual prompting bias several models toward pattern-matching on superficial lexical or visual cues rather than genuine category content. In contrast, gemini3.5 remains the most conservative model throughout, producing only 4–23 false positives per setting (an order of magnitude below the weakest open-weight models).

Fig 21 shows the F_1 scores of different models across other sets in MODERATIONBENCH. We observe that, similarly, for both open-weight and closed models, providing prototypical examples improves performance (measured in F_1) across most models when it comes to Moderated Posts, and most models outperform BMS.

For gemini, we also observe higher refusal rates (11.4% on Moderated Posts). These refusals occur before model generation, and the API returns a flag resulting from a prompt-level guardrail blocking (e.g., BlockedReason.PROHIBITED_CONTENT). Looking deeper at the refusals, we observe that posts belonging to sexual (18% of refusals), porn (17%), and nudity (15%) show higher refusals,

Figure 16: Policy quote citation distribution for gemma4 (above) and qwen3.5 (below) on Moderated Posts. Of the 177 policy quotes, 50.3% are never cited by gemma4, 47.5% by qwen3.5, and 40.1% by neither model.

Figure 17: Policy quote citation distribution for gemma4 and qwen3.5 on Moderated Posts (decision agreements).

Figure 18: Policy quote citation distribution for gemini3.5 (above) and gpt5.6 (below) on Moderated Posts. Of the 177 policy quotes, 46.9% are never cited by gemini3.5, 47.5% by gpt5.6, and 36.7% by neither model.

Figure 19: Policy quote citation distribution for gemini3.5 and gpt5.6 on Moderated Posts (decision agreements).

Figure 20: Policy citation distribution for gemini3.5 and gpt5.6 on Moderated Posts (decision disagreements).

Figure 21: F_1 score of models as **example-driven moderation** strategy varies. Bluesky does not flag any content in Near-moderated Posts, by construction.

followed by self-harm (12%) and figurative (11%). Interestingly, these are posts that contain images, and the contextual examples that are semantically similar to the inputs can potentially also be more explicit, leading to higher refusals. In contrast, gpt5.6 does not refuse any of the requests across MODERATIONBENCH.

G.2 Flagging Rates

Fig 22a shows flagging rates on Random Posts, which explains the F_1 drop from Prototypical to Contextual examples discussed in Sec. G.1. Flagging rates roughly double for some models under Contextual relative to Prototypical (e.g. gemma3: 28.1%→55.1%; llama4: 23.1%→49.2%; qwen3vl-th: 20.9%→38.9%; qwen3.5: 21.8%→33.2%), far exceeding the hu-

man annotators' flagging rate of 2.4% on this set. Since Random Posts is $\approx 97.6\%$ genuinely safe by human annotation, this increase in flagging rate is driven almost entirely by the false positives detailed in Sec. G.1 rather than by genuine recall gains. Gemini3.5 is an exception, with flagging rates staying below 6% across all three settings, the closest to the human baseline of any model.

Fig 22 further shows flagging rates across the other sets in MODERATIONBENCH. On Moderated Posts, nearly all models achieve flagging rates comparable to or exceeding human annotators, with performance above 90%. This suggests that examples reinforce the model's ability to detect harmful content.

For some models, adding examples leads to over-flagging even on Safe Posts (Fig 22c). Under random examples, qwen3vl-th shows the highest flagging on Safe Posts (22.3%, more than double any other model), while llama4 overflags most under contextual examples (30.9%, the highest of any model on Safe Posts across all settings).

G.3 Practical Efficiency

While instruction-driven moderation (Fig. 9) incurs only modest overhead from policy text, the example-driven setting introduces a much higher cost. Taking the *Labels+Rationale+Details* instruction setting as our baseline, we compare it against three example-selection strategies — *Random*, *Prototypical*, and *Contextual* - by averaging across all test sets (Figure 23). The gap is stark for both open-source and commercial API models, e.g., gemma4 rises from 0.95 s under the instruction-only baseline to 14.74 s under the *Contextual* setting, a $\sim 16\times$ increase, and qwen3.5 reaches 20.84 s, the highest latency observed across all conditions. This is an artefact of two compounding factors. First, the example-driven setups require multiple inference calls to work around context window and

Figure 22: Flagging rates(%) across all models and **example-driven moderation** strategies on different components of MODERATIONBENCH. Human annotators labeled all instances in Safe Posts as **safe**, leading to **zero flagging**.

memory constraints. Second, the contextual setting selects a distinct example set for every query, so its in-context prefix changes each time and prefix caching yields no benefit. However, random and prototypical settings use a fixed example set across queries, allowing the prefix to be cached and its cost amortized over subsequent calls. This makes the contextual setting the most expensive setting to run across all models.

Critically, for the current VLMs evaluated, this added cost buys little to no performance gain over the best zero-shot instruction-driven setting, undermining the case for example-driven moderation as a practical alternative.

Usage costs of frontier models. For gemini3.5, *Prototypical* setup cost \$112.77, *Contextual* \$493.87 and *Random* \$158.49. The second setting incurs much higher costs, possibly due to more posts containing images in the examples, compared to the other two settings. On the other hand, for gpt5.6, the costs across the three setups are \$2,000.78, \$2,553.04 and \$819.31 respectively. However, overall these costs are much higher compared to the Instruction-driven setting.

G.4 Moderation Consistency

Figures 25 and 26 (Appendix G.4) compare moderation labels predicted by the best-performing models (gemma4 and gemini3.5) as well as between

the two closed models (gemini3.5 and gpt5.6), respectively, under the best example-driven setting (prototypical). Most moderation decisions are the same between models. We quantify this consistency using Gwet’s AC1 (Fig 24). This Figure illustrates different Gwet’s AC1 agreement scores between models. Models show greater agreement with prototypical examples.

H Additional Results

H.1 Consistency Across Paradigms

We analyze shifts in gemma4’s predictions on Moderated Posts between instruction-driven (full details: *What, Why & How*) and example-driven (*Prototypical*) prompting, summarized in Figure 27. Overall, the two paradigms show *high agreement*, assigning the same label to 82.4% of posts, but diverge systematically on boundary cases. Example-driven prompting reclassifies several porn predictions as figurative (31) or sexual (9), while also predicting rude more frequently, including posts classified as Safe Posts or intolerance under instruction-driven prompting.

We further inspect the 27 cases where instruction-driven prompting predicts Safe Posts, but example-driven prompting assigns an unsafe label. Human annotations support the instruction-driven prediction in 22 of these 27 cases (81.5%). Most are classified as rude (10), intolerance (5), or graphic-media (5) by example-driven prompt-

Figure 23: Inference efficiency in the wild (Random Posts) for **example-driven** moderation settings compared to baseline (instruction-only setting with labels+rationale+details).

ing, despite containing mild profanity or insults (e.g., “Performative horseshit”, “You’re going to hell”), political and gender-identity debate commentary, or pop-culture references that human annotators judged safe. Conversely, in the remaining five cases, example-driven prompting correctly identifies content missed by instruction-driven prompting, including rude (2), graphic-media (1), sexual (1), and figurative (1) content—e.g., a politically charged slur-laden post and a poem invoking “blood sacrifice” imagery. Thus, although example-driven prompting recovers some unsafe content missed by instructions, its higher flagging rate on these disagreements primarily reflects over-flagging relative to human judgments.

H.2 Consistency of AI Safety Models

To better understand prediction differences, we analyzed disagreements between decisions of llama4 and llama-guard using the Bluesky moderation policy. In Moderated Posts and

Near-moderated Posts, llama-guard frequently misses rude and graphic-media content, even when the platform policy explicitly defines these categories. For example, it often fails to flag targeted insults and profanities as rude, whereas llama4 correctly follows the platform policy. Similarly, several nudity instances are judged non-explicit and marked safe. Figure 28 summarizes these systematic label prediction shifts. It is interesting to note how large fractions of predictions for nudity and rude from llama4 are predicted as safe by llama-guard. These changes show how llama-guard fails to be steered to catch less-explicit sexual content (nudity) or rude speech.

Model	Decision	Justification	Policy Quotes
<i>I'm a registered Green and I'm 100% for what you correctly call a coup. We VOTED for this. . . The government being taken down is as bad as any humanity has ever known. Its history of war, genocide, regime change, and mass murder is unspeakable. Kill it with fire!</i>			
gemma4	safe	Political commentary and hyperbolic language (Kill it with fire!) directed at a government entity rather than individuals; does not meet the threshold for inciting real-world harm.	"Vigorous debate, political criticism, and commentary on ideas, even harsh or provocative, are allowed. These rules do not prevent posting content that involves violence without glorifying real-world harm."
qwen3.5	threat	Explicitly calls for the government to be destroyed; Kill it with fire! constitutes incitement to violence, violating prohibitions on content that promotes or incites violence against a group.	"Threaten others with death, serious harm, or express that others should be hurt or killed. Promote, glorify, or incite violence against individuals or groups."
<i>Israel is a terrorist state that should be wiped off the face of earth</i>			
gemma4	threat	Calling for a state to be wiped off the face of earth constitutes an expression that others should be killed, violating prohibitions on advocacy of harm and incitement to violence.	"Threaten others with death, serious harm, or express that others should be hurt or killed. Promote, glorify, or incite violence against individuals or groups. The social media post shall not promote violence or harm towards others, including threats, incitement, or advocacy of harm."
qwen3.5	intolerance	Calls for the destruction of a state based on national and religious identity; constitutes incitement of hatred against a protected group, violating the Anti-Discrimination policy.	"Posts should not attack, harass, or incite hatred or discrimination based on protected characteristics including ethnicity and religious affiliation. This includes hate speech, slurs, dehumanizing comparisons, supremacist content, and coordinated harassment campaigns."
<i>Christ can lick my dirty asshole. You can too.</i>			
gemma4	intolerance	Vulgar, derogatory statement targeting a central figure of Christianity; constitutes an attack based on religious affiliation, violating the Anti-Discrimination policy.	"Social media posts should not attack, harass, or incite hatred or discrimination against individuals or groups based on protected characteristics such as religious affiliation."
qwen3.5	rude	Sexually graphic crude language directed at a religious figure without constructive purpose; not substantive criticism or debate, violating the prohibition on rude or impolite content.	"The social media post shall not contain rude or impolite content, including crude language and disrespectful comments, without constructive purpose. Content that is harsh but has substantive criticism without intent to attack is allowed."
<i>sTump wants a fight. Talks and acts like a fucking weak ass prick low life sob. . . Useless. Decades. Useless.</i>			
gemma4	rude	Multiple personal attacks and crude epithets (prick, low life sob, coward filth) without constructive political substance; violates prohibition on repeated ad hominem insults.	"The social media post shall not contain crude language and disrespectful comments without constructive purpose. Extreme or repeated personal attacks such as insults or ad hominem attacks are prohibited."
qwen3.5	safe	Harsh political criticism of public figures; crude language used in political commentary does not constitute harassment or incitement of harm and falls within the allowance for vigorous debate.	"Content that is harsh but has substantive criticism or debate without an intent to attack is allowed. Content containing impolite or crude language used as exaggeration or a figure of speech is allowed and should not be labeled."
<i>Punching nazis should be as American as baseball and apple pie</i>			
gemma4	threat	Advocates for physical violence; promotes, glorifies, or incites violence against individuals or groups, and constitutes advocacy of harm.	"A social media post should not: Promote, glorify, or incite violence against individuals or groups. The social media post shall not promote violence or harm towards others, including threats, incitement, or advocacy of harm."
qwen3.5	safe	A general political opinion rather than a specific threat; vigorous debate and political criticism, even when provocative, are allowed when they do not cross into direct attacks or immediate real-world harm.	"Vigorous debate, political criticism, and commentary on ideas, even harsh or provocative, are allowed. Content that is harsh but has substantive criticism or debate without an intent to attack is allowed and should not be labeled."
<i>God, can that bullet hit you and all the uneducated retards who believe this. . .</i>			
gemma4	intolerance	Uses slur <i>retards</i> to dehumanize a group based on disability; violates Anti-Discrimination policy prohibiting hate speech and slurs targeting protected characteristics.	"Social media posts should not attack, harass, or incite hatred or discrimination based on protected characteristics. This includes hate speech, slurs, dehumanizing comparisons, supremacist content, and coordinated harassment campaigns."
qwen3.5	threat	Explicitly wishes a bullet would strike a group of people; constitutes a direct threat of death or serious harm, violating prohibitions on promoting violence or harm towards others.	"Threaten others with death, serious harm, or express that others should be hurt or killed. The social media post shall not promote violence or harm towards others, including threats, incitement, or advocacy of harm."

Table 8: Representative disagreement cases between gemma4 and qwen3.5. Post background indicates inter-annotator agreement: both agree (Decision & Quotes) , both disagree , agree on Quotes only , agree on Decision only . **Bold** indicates the annotator-preferred justification or policy quotes. Only text-based instances are shown in the paper owing to the significantly disturbing nature of visually unsafe posts.
